Quantitative Analysis of *Unawakened Crown* (In respect to version v0.2.5_EA)

Abstract

Based on the current playtest data, the core mechanism and basic gameplay loop of Unawakened Crown has potential, but there are still several obvious imbalances in terms of values, rhythm, and player interaction. In the current version, stable decision-making pressure has not yet been formed in terms of movement, event density, attack card supply, damage to health ratio, and the profit structure of some event options. These issues will diminish the significance of player actions.

This analysis summarizes the current issues into several main findings: the dead roll issue in the original movement formula; the high proportion of Blank Events that dilute the events that truly have the value of choice, reward, or conflict; unengaging PvP not only because of low damage, but also because the probability of attack and interference cards entering the player's hand is too low; inconsistent damage and HP values; and the event options having a 100% or 0% selection rate, indicating that they have not formed a true dilemma.

Therefore, the next version should prioritize that movement actions making genuine progress, reducing the density of Blank Events, increasing the supply of attack/interference cards, unifying the HP baseline, and redesigning event options that are clearly too strong or completely unselected. The next round of playtest should focus on tracking the average game length, event resolution rate, number of attack cards obtained, actual number of attacks, total damage, player's final HP, and distribution of event options.

1. Quantitative Profile

The current dashboard contains approximately 22 playtest data sets. Although the sample size is not yet large and may include both 2-player and 3-player games, these data are sufficient as a reference for the design defense line in the prototype stage. The overall data can be used to observe the current pace of the game, event handling, and whether player conflicts have truly occurred.

Based on the existing data, the average number of turns is about 10.32, and the average round is about 5.45. The overall event resolution rate is about 68-70%, and the event ignore rate is about 16%. This indicates that most events can be handled during the game, but there are still some events that players may ignore or leave until the end of the game. There are also about 17 unresolved events in the dashboard, indicating that there may still be issues with insufficient event motivation, high processing costs, or too fast a process pace that leaves players unable to handle events in time.

More importantly, the value of destroyed cards in the dashboard is 0. This indicates that in the current version, card destruction, attack, interference, or PvP related mechanisms have not yet formed a stable revenue relationship.

Therefore, the following analysis will explain the current balance problem from five aspects: movement, event density, attack supply, HP scaling, and event choice structure.

2. Movement Balance and Dead Rolls

Roll	Number of discarded path cards	probability
1	0 cards	16.67%
2–3	1 card	33.33%
4–5	2 cards	33.33%
6	3 cards	16.67%

The chart above shows the initial design of probability for the “movement” mechanic. The problem with this design is that when the player throws 1, the movement result is 0. 16.67% may not seem particularly high in mathematics, but it is already enough to affect the actual rhythm in actual gameplay. Especially when the player has no other effective actions in this round, the dead roll will make the entire turn boring and severely frustrated.

To address this issue, we suggest switching to a progressive movement chart that directly eliminates the possibility of 0 progress:

Roll	Number of discarded path cards	probability
1–2	1 card	33.33%
3–4	2 cards	33.33%
5–6	3 cards	33.33%

This amendment has two advantages. Firstly, it ensures progress with each movement, avoiding a wasted action. Secondly, it makes mobile revenue stable and easier for players to understand. The average moving income of the original formula is about 1.5 path cards, while the average moving income of the new table is 2 path cards.

However, this change may also make the overall pace of the game. Thus, if the game ends too quickly, we can control the pace by increasing the path deck length, adjusting event processing costs, or requiring additional processing for some events after they enter the pending area.

3. Blank Events

The Blank Event itself is not a design error. It is used to control the rhythm and avoid players encountering complex events every step forward. However, the issue with the current version is the high proportion of Blank Events, which leads to severe dilution of the content that truly generates choices, rewards, or conflicts in the path deck.

Each player's path deck target is approximately 20 cards. Among them, 12 event cards have already been configured, and the system will use an additional 8 Blank Events to supplement the path deck. Meanwhile, as the configuration already includes 3 Blank Events, approximately 11 Blank Events will appear in the player's actual path deck, accounting for about 55%.

There is a more than a 50% chance that players will not encounter truly meaningful events every time they advance the path deck. In this situation, players often simply clear their cards mechanically, rather than making choices, receiving rewards, taking risks, or interacting with other players.

Therefore, the next version suggests reducing the Blank Event ratio from approximately 55% to 25-30%. If the path deck remains at 20, it would be more appropriate to control the number of Blank Events at around 5-6.

4. Attack Card Supply and PvP Economy

Damage and HP need to be rebalanced in order for attacking to be a meaningful part of gameplay. As it stands, players in the beginning of the game start with a base of 100HP, while common attacks and scripted events do anywhere from 2-6HP of damage. These numbers make attacks largely insignificant and reduce the importance of health management. If these dynamics were to be adjusted, it would make the board game more enjoyable since eliminating your opponents before they reach the ending creates higher stakes and interesting player interactions.

Moreover, in the current version, PvP is also weak because the probability of attack and interference cards entering the player's hand is too low, resulting in a lack of stable tools even if the player wants to actively attack.

According to current estimates, events that can provide stable hand resources or indirectly bring attack resources mainly include Treasure Chest, Cart Dilemma, Banshee, Cyclops, etc., with a total of about 6 cards, accounting for about 30% of the 20 path decks. However, even if players encounter these events and successfully resolve them, the proportion of attack/interference cards that actually enter the hand pool is only about 30%, of which the proportion of cards that can directly cause HP damage is even lower, about 15%.

If combined with the current event resolution rate of approximately 68-70%, the probability of a player opening a path card expecting to receive an attack/interference card is only about 6%; The probability of obtaining a direct damage card is only about 3%.

Convert to a full round of 20 path cards:

Indicator	Current estimate	Meaning
------------------	-------------------------	----------------

Attack / Interference card chance	$\approx 6\%$	The probability of obtaining attack or interference tools is very low for every path card opened
Direct damage card chance	$\approx 3\%$	There are fewer cards that can truly cause HP damage
20-card path deck EV	$20 \times 6\% = 1.2$ cards	On average, there are only about 1.2 attack/interference cards in a whole game
Direct damage EV	$20 \times 3\% = 0.6$ cards	Less than 1 direct damage card on average in a whole game
Destroyed cards in dashboard	0	The conflict and card destruction mechanism have not formed a stable profit chain

This result indicates that even if the player's HP is reduced to 20 or 30, if the player can only receive an average of less than 1 valid damage card throughout the game, it is still difficult to truly kill the opponent. That is to say, simply increasing damage or reducing HP cannot solve the PvP problem. Players first need to obtain attack tools more stably, otherwise the attack system cannot be fully tested.

Therefore, in the next version, we must establish an independent Attack/Interference reward pool. Treasure Chest, Cyclops, Banshee, Cart Dilemma, and other events can be dealt from this reward pool instead of relying entirely on a regular hand pool. And attacks not only cause damage, but also affect progress. Some attack cards can cause 2-4 damage, while causing the target to discard 1 less path card, lose 1 Attention, or randomly display 1 hand in their next move. In the revenue section, we have decided to allow players to view the hand of the killed player when killing them, and to select and obtain 1-3 cards from them.

5. Dominant Options and Dead Options

There is also an issue with the event card. A good dilemma is not about letting players see at a glance which option is optimal, but about making each choice have both benefits and costs. But there are multiple 100%/0% selection rates in the current dashboard, indicating that some event options have not truly formed decisions.

The three choice event does not necessarily need to achieve a perfect average of 33/33/33, but it should not persist for a long time at 100/0/0.

6. Conclusion

Overall, the current data indicates that the problem with Unawaken Crown is not that a single value is too high or too low, but rather that a stable revenue chain has not yet formed

among several systems. Mobile needs to ensure progress, events need to provide sufficient density, attacks need to have stable supply, HP and damage need to use the same baseline, and event options need to truly form a trade-off.

The goal of the next round of playtest should be to verify whether these changes allow players to have more meaningful actions: whether they encounter real events more frequently, whether they are more willing to actively attack, whether they make different choices based on resource status, and whether the game still maintains an appropriate length.
